UNU-IIST and UNU-IIST Reports

UNU-IIST (United Nations University International Institute for Software Technology) is a Research and Training Centre of the United Nations University (UNU). It is based in Macau, and was founded in 1991. It started operations in July 1992. UNU-IIST is jointly funded by the Governor of Macau and the governments of the People's Republic of China and Portugal through a contribution to the UNU Endowment Fund. As well as providing two-thirds of the endowment fund, the Macau authorities also supply UNU-IIST with its office premises and furniture and subsidise fellow accommodation.

The mission of UNU-IIST is to assist developing countries in the application and development of software technology.

UNU-IIST contributes through its programmatic activities:

1. Advanced development projects, in which software techniques supported by tools are applied,
2. Research projects, in which new techniques for software development are investigated,
3. Curriculum development projects, in which courses of software technology for universities in developing countries are developed,
4. University development projects, which complement the curriculum development projects by aiming to strengthen all aspects of computer science teaching in universities in developing countries,
5. Schools and Courses, which typically teach advanced software development techniques,
6. Events, in which conferences and workshops are organised or supported by UNU-IIST, and
7. Dissemination, in which UNU-IIST regularly distributes to developing countries information on international progress of software technology.

Fellows, who are young scientists and engineers from developing countries, are invited to actively participate in all these projects. By doing the projects they are trained.

At present, the technical focus of UNU-IIST is on formal methods for software development. UNU-IIST is an internationally recognised center in the area of formal methods. However, no software technique is universally applicable. We are prepared to choose complementary techniques for our projects, if necessary.

UNU-IIST produces a report series. Reports are either Research [R], Technical [T], Compendia [C] or Administrative [A]. They are records of UNU-IIST activities and research and development achievements. Many of the reports are also published in conference proceedings and journals.

Please write to UNU-IIST at P.O. Box 3058, Macau or visit UNU-IIST's home page: <http://www.iist.unu.edu>, if you would like to know more about UNU-IIST and its report series.

POST: A Case Study for rCOS Incremental Development

Quan Long, Zongyan Qiu, Zhiming Liu, Lingshuang Shao, and He Jifeng

Abstract

We have recently developed an object-oriented refinement calculus called rCOS. With rCOS, we formalize the object-oriented design principles and patterns as refinement laws. rCOS has been proven to provide formal support to software design and program refactoring. All these features together show that rCOS can be used as a formal framework for the *use-case driven*, *incremental* and *iterative* Rational Unified Process (RUP). In this paper, we apply rCOS to a step-wised development of a Point of Sale Terminal (POST) system and demonstrate how to apply the refinement laws for design and refactoring, from a requirement model to a design model, and finally, to the implementation in Visual C#.

Quan Long is an ex-fellow of UNU-IIST from Peking University, Beijing, China, where he is a doctoral candidate. His research interests include programming languages, software development and formal techniques for Object Oriented, UML and Component Software.

Zongyan Qiu is a professor of computer science at the Department of Informatics, School of Mathematical Sciences of Peking University. His research interests include semantics, formal methods and programming languages.

Zhiming Liu is a Research Fellow at UNU/IIST, on leave from Department of Computer Science at the University of Leicester, Leicester, England where he is lecturer in computer science. His research interests include theory of computing systems, emphasising sound methods for specification, verification and refinement of fault-tolerant, real-time and concurrent systems, and formal techniques for OO development. His teaching interests are Communication and Concurrency, Concurrent and Distributed Programming, Internet Security, Software Engineering, Formal specification and Design of Computer Systems.

Lingshuang Shao is a master student of Peking University. His research interests include software engineering and programming languages.

He Jifeng is a Senior Research Fellow of UNU/IIST. He is also a professor of computer science at East China Normal University and Shanghai Jiao Tong University. His research interests include the Mathematical theory of programming and refinement methods, design techniques for the mixed software and hardware systems.

1 Introduction

In the imperative paradigm, the *specification* of the problem is mainly concerned with the control and data structures of the program. The program development is the design and implementation of data structures and algorithms through a number of steps of *refinement*. *Verification* is needed to prove that each step preserves the specification of the control and data structures in the previous step. Various formal methods, especially those state-based models [5, 10] such as VDM [11] and Z [4], are widely found helpful in correct and reliable construction of such a program.

The object-oriented requirement analysis, design and programming are popular recently in practical software engineering. Recent development and application of UML and the Rational Unified Process (RUP) have led to the use of design patterns and refactoring more effective.

However, the research in the formal aspects and techniques does not reflect or provide enough support to these newly developed object-oriented engineering principles and development processes. It is still hard to obtain assurance of correctness in object-oriented developing process using old fashioned programming techniques. Model-based formalisms have been extended with object-oriented techniques, via languages such as Object-Z [1], VDM++ [6], and methods such as Syntropy [3] which uses the Z notation, and Fusion [2] that is related to VDM. Whilst these formalisms are effective at modelling data structures as sets and relations between sets, they do not capture the main principles of object-oriented decomposition, including functionality delegation, class decomposition, and object-oriented refinement. Object-oriented refinement must capture the notation of substitutability of a group of associated classes by another group of associated classes. The development of rCOS is mainly motivated by these problems.

rCOS includes a specification notation that allows us to specify object-oriented systems at different levels of abstraction. The notation has a relational denotational semantics based on Hoare and He's Unifying Theories of Programming (UTP) [10]. Object-oriented specifications of a system at different levels of abstraction are related by the *refinement relation* between object-oriented designs. We have proven refinement laws [9] that reflect the basic object-oriented design principles including those five GASP design patterns presented in Larman's book [12]. The design patterns in [8] and laws of refactoring in Fowler's book [7] can also be proven to be refinement laws [16]. One of the main features of rCOS, say, its supporting use-case driven, incremental and iterative development, came from our earlier work on object-oriented requirement analysis [13, 15]. Those papers also show how rCOS can be applied to formal support of UML-based development.

In this paper, we use the case study of a Point of Sale Terminal (POST) system, originally from [12] to demonstrate how a system can be formally and systematically developed. A POST system is typically used in a retail store or supermarket. It includes hardware components such as a computer and a bar code scanner, and the software to control the system. The case study also shows how the techniques could be used in the development of other systems.

The rest of this paper is organized as follows. We first briefly introduce rCOS and related notions in Section 2. And then, in Section 3, we present our development process, or refinement process of POST software system. The executable product developed from our final refined design is illustrated in Section 4. Finally, in Section 5, we conclude the paper and discuss some future research directions.

2 Overview of rCOS

In this section we give a brief introduction to the rCOS model and our earlier work based on it. We refer the readers to [9, 15] for more details.

2.1 rCOS Syntax

rCOS is a refinement calculus of *object-oriented sequential systems*. In rCOS, a system (or program) S is of the form $cdecls \bullet P$, consisting of class declaration section $cdecls$ and a main method P . The main method P is a pair (\mathbf{glb}, c) of a set \mathbf{glb} of *global variables declarations* and a command c . P can also be understood as the *main method* in Java. The class declaration section $cdecls$ is a sequence of class declarations $cdecl_1; \dots; cdecl_k$, where each class declaration $cdecl_i$ is of the form

```
[private] class  $N$  extends  $M$  {
  private  $(U_i u_i = a_i)_{i:1..m}$ ; protected  $(V_i v_i = b_i)_{i:1..n}$ ; public  $(W_i w_i = c_i)_{i:1..k}$ ;
  method  $m_1(\underline{T}_{11} \underline{x}_1, \underline{T}_{12} \underline{y}_1, \underline{T}_{13} \underline{z}_1)\{c_1\}; \dots; m_\ell(\underline{T}_{\ell 1} \underline{x}_\ell, \underline{T}_{\ell 2} \underline{y}_\ell, \underline{T}_{\ell 3} \underline{z}_\ell)\{c_\ell\}$ 
```

Note that

- A class can be declared as **private** or **public**, but by default it is assumed as **public**. Only the public classes and primitive types can be used in the global variable declarations \mathbf{glb} .
- N and M are distinct names of classes, and M is called the direct superclass of N .
- Attributes annotated with **private** are private attributes of the class, and similarly, the **protected** and **public** declarations for the protected and public attributes. Types and initial values of attributes are also given in the declaration.
- The method declaration declares the methods, their value parameters $(\underline{T}_{i1} \underline{x}_i)$, result parameters $(\underline{T}_{i2} \underline{y}_i)$, value-result parameters $(\underline{T}_{i3} \underline{z}_i)$ and bodies (c_i) . We sometimes denote a method by $m(\underline{paras})\{c\}$, where \underline{paras} is the list of parameters of m , and c is the body command of m . The method body c_i is a command that will be defined later.

We use Java convention to write a class specification, and assume an attribute **protected** when it is not tagged with **private** or **public**. We have these different kinds of attributes to show

how visibility issues can be dealt with. We can also have different kind of methods for a class, however, it is omitted here for simplicity of the theory. Instead, we assume all methods in public classes are public and can be inherited by a subclass and accessed by the main method, and all methods in private classes are protected.

When we write refinement laws, we use the following notation to denote a class declaration of class N .

$$N[M, \text{pri}, \text{prot}, \text{pub}, \text{op}]$$

where M is the name of the direct superclass of N , **pri**, **prot** and **pub** are the sets of the private, protected and public attribute declarations, and **op** is the set of the method declarations of N . When there is no confusion, we only explicitly give the parameters that we are concerned. For example, we use $N[\text{op}]$ to denote a class with a set **op** of methods, and $N[\text{prot}, \text{op}]$ a class with a protected attributes **prot** and methods **op**.

2.1.1 Commands

rCOS supports typical object-oriented programming constructs, but it also allows some commands for the purpose of specification and refinement:

$$c ::= \text{skip} \mid \text{chaos} \mid \mathbf{var} \ T \ x=e \mid \mathbf{end} \ x \mid c; c \mid c \triangleleft b \triangleright c \mid c \sqcap c \\ \mid b * c \mid le.m(\underline{e}, \underline{v}, \underline{u}) \mid le := e \mid C.new(x)[\underline{e}]$$

where b is a Boolean expression, e is an expression, and le is an expression which may appear on the left side of an assignment and is of the form $le ::= x \mid le.a$, where x is a simple variable and a an attribute of an object. We use $le.m(\underline{e}, \underline{v}, \underline{u})$ to denote a call of method m of the object denoted by le with actual value parameters \underline{e} for input to the method, actual result parameters \underline{v} for the return values, and value-result parameters \underline{u} that can be changed during the execution of the method and with their final values as return values too. The command $C.new(x)[\underline{e}]$ creates a new object of class C with the initial values of its attributes assigned by the values of the expressions in \underline{e} and assigns it to variable x . Thus, $C.new(x)[\underline{e}]$ uses x with type C to refer to the newly created object.

The expressions e appear in the commands are defined in a usual way. We ignore them here.

2.2 Semantics and Refinement of Object Systems

rCOS adopts an observation-oriented and relational semantics. The model describes the behavior of an object-oriented program by a *design* containing seven logical variables as its *free vari-*

ables that form the *alphabet* “ α ” in [10] of the program. They are **cname**, **attr**, **op**, **superclass**, **Σ** , **glb** and **locvar**. They record both static structure of the classes and dynamic state of the system.

Commands and class declarations, as well as an object system as a whole, are semantically defined as a *framed design* $D(\alpha, P)$ with the form $\{\alpha\} : pre(x) \vdash Post(x, x')$. That is, the effect of any piece of code are defined by the pre- and post states of the above mentioned *alphabet*. Please see [9] for details if interested.

Based on the relational model, rCOS supports refinement of object-oriented designs at different levels of abstraction during a system development. It includes design refinement, data refinement, refinement of classes and refinement of a whole system.

In [9], the *Design refinement* and *Data refinement* are defined similar to traditional ones. In this section we only present the definitions of *System refinement* and *Class refinement* as follows.

Definition 2.1 (System refinement) Let S_1 and S_2 be object programs which have the same set global variables **glb**. S_1 is a *refinement* S_2 , denoted by $S_1 \sqsubseteq_{sys} S_2$, if its behavior is more controllable and predictable than that of S_2 :

$$\forall \underline{x}, \underline{x}' \cdot (S_1 \Rightarrow S_2)$$

where \underline{x} are variables in **glb**.

This indicates the external behavior of S_1 , that is, the pairs of pre- and post global states, is a subset of that of S_2 . To prove one program S_1 refines another S_2 , we require that they have the same set of global variables and the existence of a *refinement mapping* between the variables of S_1 to those of S_2 that is identical on global variables.

Definition 2.2 (Class refinement) Let $cdecls_1$ and $cdecls_2$ be two declaration sections. $cdecls_1$ is a *refinement* of $cdecls_2$, denoted by $cdecls_1 \sqsubseteq_{class} cdecls_2$, if the former can replace the later in any object system:

$$cdecls_1 \sqsubseteq_{class} cdecls_2 =_{df} \forall P \cdot (cdecls_1 \bullet P \sqsubseteq_{sys} cdecls_2 \bullet P)$$

where P stands for a main method (**glb**, c).

Intuitively, it states that $cdecls_1$ supports at least the same set of services as $cdecls_2$.

As stated in the introduction section, in our earlier work [9] and [16], we have given many useful refinement laws that capture the nature of incremental development in object-oriented programming. Please refer to them if interested.

2.3 rCOS Based Development Process

In the next section, we will formalize the incremental development process as a step wise refinement process. Before that, we include here a brief overview of the rCOS based development process, which is the back ground of the refinement. For more details, please refer to [15].

The incremental development initiates in the requirement analysis to reach the *Use Cases* of the system [13], then, the *Conceptual Model* and *Design Model* [15, 14] are built sequentially. From an informal view, a *Conceptual Model* can be thought as a class diagram in which all classes have only attributes without methods, and *Design Model* a class diagram in which all classes have attributes and method specifications (not necessarily code) as well. The development from *Conceptual Model* to *Design Model* is composed of the following phases:

1. Chose some classes as *Use Case Controllers* and develop the specifications of the use cases as the method specifications of these controllers.
2. Develop the relative methods in some other classes, delegate the tasks of the controller classes to those classes.
3. Further, develop methods and delegate tasks of those classes iteratively.

Getting the *Design Model*, we can improve the flexibility and maintainability further by refactoring [7, 16]. And at last, we implement it by an OO programming language.

2.4 Some Laws and Notations

We introduce some laws in [9] and [16] with respect to the usage of this paper.

Law 1 (Law 7. in [9]) Introducing a private attribute has no effect) *If neither N nor any of its superclasses and subclasses in $cdecls$ has x as an attribute, then*

$$N[priv]; cdecls \sqsubseteq N[priv \cup \{T \ x = d\}]; cdecls.$$

Law 2 (Law 8. in [9]) Changing private attributes into protected supports more services)

$$N[priv \cup \{T \ x = d\}, prot]; cdecls \sqsubseteq N[priv, prot \cup \{T \ x = d\}]; cdecls.$$

Law 3 (Law 9. in [9]) Adding a new method refines a declaration) *If m is not in N , let $m(paras)\{c\}$ be a method with distinct parameters $paras$ and a command c , then*

$$N[ops]; cdecls \sqsubseteq N[ops \cup \{m(paras)\{c\}\}]; cdecls$$

Law 4 (Law 10. in [9] Refining a method refines a declaration) *If $c_1 \sqsubseteq c_2$,*

$$N[\text{ops} \cup \{m(\text{paras})\{c_1\}\}]; \text{cdecls} \sqsubseteq N[\text{ops} \cup \{m(\text{paras})\{c_2\}\}]; \text{cdecls}$$

Law 5 (Law 1. (Extract Method) in [16]) *Assume that $m_1()\{c\}$ is a method in op of class M . Let $\text{op}_1 = \text{op} \setminus \{m_1()\{c\}\}$. Then*

$$\text{cdecls}; M[\text{op}_1 \cup \{m_1()\{m_2()\}, m_2()\{c\}\}] \sqsupseteq \text{cdecls}; M[\text{op}]$$

where m_2 is a method name that is not used in cdecls and op .

Law 6 ((Law 10. (Move Method) in [16]) *Let op and op_1 be sets of method declarations. Assume that $N b$ is an attribute of M , and $m()\{\hat{c}\}$ is a method of M , $m()$ is not in op_1 of N , and command c only refers attributes $b.x$ and methods $b.n()$ of class N . Define*

- $\hat{\text{op}}$ to be the methods obtained from op by replacing each occurrence of $m()$ in every method with $b.m()$
- command c to be the command obtained from \hat{c} by replacing each attribute $b.x$ with x and each method call $b.n()$ with $n()$.

$$\begin{aligned} & \text{cdecls}; M[N b, \hat{\text{op}}]; N[\text{op}_1 \cup \{m()\{c\}\}] \\ & \sqsupseteq \text{cdecls}; M[N b, \text{op} \cup \{m()\{\hat{c}\}\}]; N[\text{op}_1] \end{aligned}$$

provided that $m()$ is not called from outside M on the right-hand-side of \sqsupseteq .

Law 7 ((Law 12. (Extract Class) in [16]) *Assume N is a fresh name which is not used in cdecls and $m_2()$ does not refer any attribute of M . Then we have*

$$\text{cdecls}'; M[N n, \hat{m}_1()]; N[m_2()] \bullet P' \sqsupseteq \text{cdecls}; M[m_1(), m_2()] \bullet P$$

where cdecls' is gain from cdecls by substitute all $M.m_2()$ to $N.m_2()$, P' is gain from P by substitute all $M.m_2()$ to $N.m_2()$, and $\hat{m}_1() = m_1()[n.m_2()/m_2()]$.

Law 8 ((Law 59. (Strategy) in [16]) *Assume all the newly introduced names are fresh ones. We have*

$$\begin{aligned} & \text{Context}[\text{Strategy } s, \text{op}()]; \text{Strategy}[\text{algorithm}()]; \text{StrategyA}[\text{algorithm}()]; \text{StrategyB}[\text{algorithm}()] \\ & \sqsupseteq \text{Context}_0[\text{Strategy } s, \text{op}()]; \text{Strategy}[\text{algorithm}_0()] \end{aligned}$$

where

- $op() =_{df} \{s.algorithm()\}$.
- In class *StrategyA*, $algorithm() =_{df} \{c_A\}$, where c_A is a sequence of commands for a particular algorithm.
- In class *StrategyB*, $algorithm() =_{df} \{c_B\}$, where c_B is a sequence of commands for another particular algorithm.
- $algorithm_0() =_{df} \{c_A \triangleleft b \triangleright c_B\}$, where b is a boolean variable for making a choice between algorithm c_A and c_B .

Finally, we have a shorthand notation $\exists o : T$ which stands for the existing of a reference o which refers to an object of type T . It can be formally defined using rCOS semantics. We use it here to replace the standard notations for simplicity and intuition. Also, we do not have *return* keyword in the syntax of rCOS. But it can be defined using local variable declaration. We will use it for intuition.

3 POST: Incremental Development as Step Wise Refinement

In this section, we present our incremental development as a sequence of refinement steps. During the development, we always denote the system as a sequence of class declarations. Initially, *POST0* stands for the first naive version of the system. And then, with the support of the refinement laws above, we refine it to *POST1*. Similarly, *POST1* can be refined to *POST2*. At last, the system reaches *POST7* which is the final version of the design. Intuitively, each version of the sequence of class declarations is depicted by a corresponding UML class diagram.

3.1 Initial “System”

At the beginning, we should determine the basic components of the system. After the requirement analysis, we decide to have the classes as follows: A *Product Catalog* as a database to store the information of all possible on sale products of the given supermarket. Each item of the database is a *Product Specification*. When a sale begins, we need to build a *Sale* object which is composed of many *Sales Line Item* to record all the products purchased. At last, the customer has to make a payment. Thus we need another object *Payment*. During the execution, we will create many instances of *Sale*, *Sales Line Item*, and *Payment*. Finally, we need a class as the user interface which is the *use case controller* of the system. We name it as *Post*. After a slight analysis of the relationship between the above mentioned six classes, we have the “class diagram” in Fig. 1. The textual representation is as follows

$$POST0 = \text{Post}[\]; \text{ProductCatalog}[\]; \text{ProductSpecification}[\]; \\ \text{Sale}[\]; \text{SalesLineItem}[\]; \text{Payment}[\];$$

Figure 1: Initial “System”

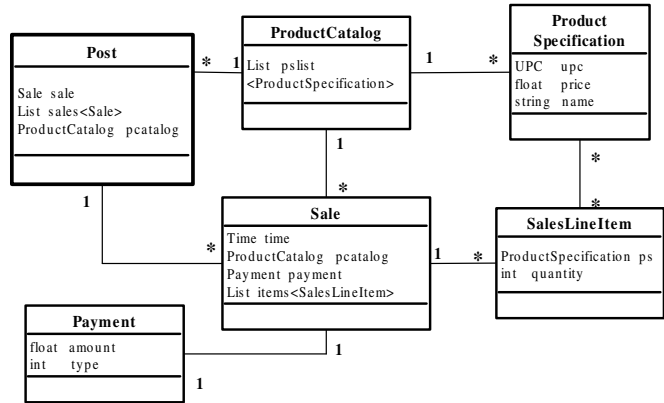

Figure 2: Conceptual Model

3.2 Conceptual Model

The classes in *POST0* do not have any attribute. Our first job is to add them. During the requirement analysis, we realize that these classes should have attributes as follows:

- *Post*, which act as the interface of the system, should maintain at least three attributes: *sale* refers to the current sale object, *sales* as a list of sale objects to record all the handled sales, and a reference to the database *ProductCatalog*.
- *ProductCatalog* has a list of references to its *ProductSpecifications*.
- *ProductSpecification* should have a *name*, an attribute *upc* which stands for “Universal Product Code” as its key in the database, and another attribute *price*.
- *Sale* should have at least four attributes: a business time *time*, a reference to *ProductCatalog*, a reference to the *payment* object and a list of its *SalesLineItem*.
- *SalesLineItem* should have a reference to its corresponding *ProductSpecification* and a integer, *quantity*, to record how many products of this kind are purchased.
- The last class, *Payment* should remember how much money the customer should pay in its attribute *amount* and the payment way in *type*. Here we only deal with two kinds of payment: *type* = 0 stands for pay by cash and *type* = 1 for pay by credit card.

In our relational OO model, we can add private attributes and change a private attribute into a protected one by **Law 1** and **Law 2**. For example, suppose *cdecls* stands for the other classes except for *Post*, we have

$$Post[]; cdecls \sqsubseteq Post[\mathbf{pri} Sale sale]; cdecls \dots \dots \dots \mathbf{Law 1}$$

and $Post[\mathbf{pri} Sale sale]; cdecls \sqsubseteq Post[\mathbf{prot} Sale sale]; cdecls \dots \dots \dots \mathbf{Law 2}$

We can apply these laws repeatedly to add all the above mentioned attributes to our classes.

Thus we reach the class diagram in which all the attributes have been filled in their corresponding classes, that is the *Conceptual Model* of the system. Fig. 2 illustrated the class diagram.

We denote the classes depicted in Fig. 2 as $POST1$ which is a sequence of class declarations. As proved formerly, we have $POST0 \sqsubseteq POST1$.

3.3 Use case Controller Class

Having the *Conceptual Model*, $POST1$, now we consider to refine the system to the *Design Model* which includes all the method specifications. We start from the controller class *Post*. As the result of the *use case* analysis, we realize that *Post* has to offer at least five methods: *makeSale()* to initiate a business by creating a new object *sale* of type *Sale*; *enterItem()* to add a sale line item to the *sale* object; *makePayment()* to summarize the price and create a *payment* object; *printSale()* and *endSale()* to print and end the business respectively. Further, *endSale()* has another job which is adding the reference of current *sale* object to the *sales* list.

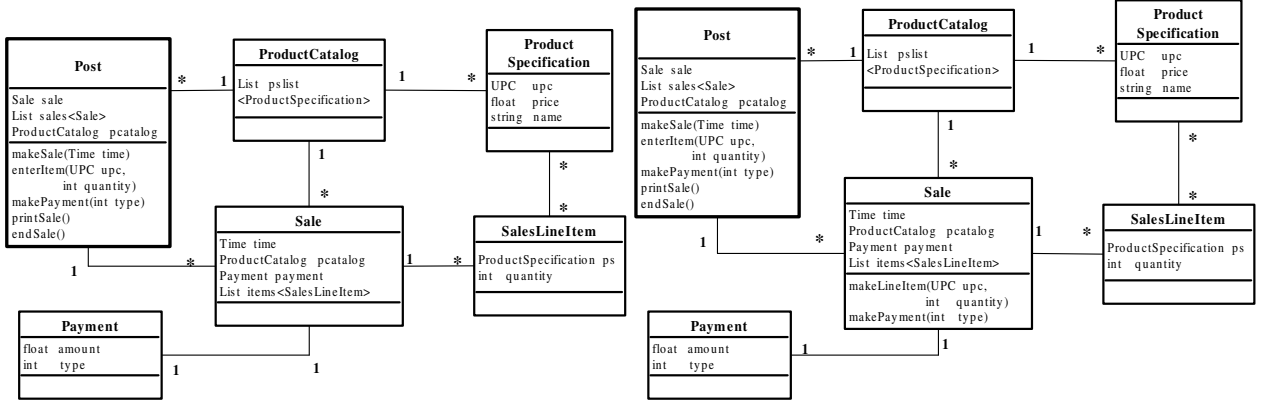

Here we formally give the details of the method specifications as follows:

- *makeSale(Time time)*
 $pcatalog \neq nil \vdash sale'.time = time \wedge sale'.pcatalog = pcatalog$
- *enterItem(UPC upc, int quantity)*
 $pcatalog \neq nil \wedge sale \neq nil \wedge quantity \neq 0 \vdash$
 $\exists item : SalesLineItem \bullet sale.items' = sale.items \cup \{item\}$
 $\wedge item.upc = upc \wedge item.quantity = quantity$
 $\wedge (\exists ps : ProductSpecification \bullet ps \in pcatalog \wedge item.ps = ps \wedge ps.upc = upc)$

- *makePayment(int type)*
 $sale \neq nil \wedge type \in \{0, 1\} \vdash$
 $\exists payment : Payment \bullet sale.payment' = payment$
 $\wedge payment.amount = \sum_{item \in items} item.ps.price \times item.quantity$
 $\wedge ((type = 0 \wedge \{\text{Paid by cash}\}) \vee (type = 1 \wedge \{\text{Paid by credit}\}))$

where $\{\text{Paid by cash}\}$ stands for customer's completion of paying by cash, and $\{\text{Paid by credit}\}$ stands for customer's completion of paying by credit card.

- *printSale()*
 $sale \neq nil \wedge done(makePayment) \vdash \{\text{Print the sales line item report}\}.$
 where the predicate $done(makePayment)$ means the customer has made payment, and $\{\text{Print the sales line item report}\}$ stands for printing the receipt for customer.
- *endSale()*
 $sale \neq nil \wedge done(makePayment) \vdash sale' = nil \wedge sales' = sales \cup \{sale\}$

The class diagram is depicted in Fig. 3. We denote the corresponding class declarations as $POST2$. With the support of **Law 3** we can prove that adding a method is a refinement to the system. So, trivially, applying this law five times, we have $POST1 \sqsubseteq POST2$.

3.4 Design Model

Having added the interface methods to the system, the next task we confront with is to develop all the methods of the classes to complete our *Design Model*.

Firstly, we delegate some of the tasks of $Post$ to $Sale$. To achieve this, we first develop the following two methods in the class $Sale$. For the same reason to subsection 3.3, the new system added these methods refines the former version.

- $makeLineItem(UPS\ ups, int\ quantity)$
 $pcatalog \neq nil \wedge quantity \neq 0 \vdash$
 $\exists item : SalesLineItem \bullet items' = items \cup \{item\} \wedge item.upc = upc \wedge item.quantity = quantity$
 $\wedge (\exists ps : ProductSpecification \bullet ps \in pcatalog \wedge item.ps = ps \wedge ps.upc = upc)$
- $makePayment(int\ type)$
 $type \in \{0, 1\} \vdash \exists payment : Payment \bullet payment' = payment$
 $\wedge payment.amount = \sum_{item \in items} item.ps.price \times item.quantity$
 $\wedge ((type = 0 \wedge \{Paid\ by\ cash\}) \vee (type = 1 \wedge \{Paid\ by\ credit\}))$

Secondly, we can implement, or refine, in our model, the methods $enterItem()$, and $makePayment()$ in class $Post$ by invoking the above developed methods as follows:

- $enterItem'(UPC\ upc, int\ quantity) = \{sale.makeLineItem(upc, quantity)\}$

- $makePayment'(int\ type) = \{sale.makePayment(type)\}$

Now after adding the methods $makeLineItem()$ and $makePayment()$ to the class $Sale$, we substitute $enterItem()$, $makePayment()$ with $enterItem'()$, $makePayment'()$ in class $Post$. We denote the new system as $POST3$.

Using the semantic model of [9], we can prove that in class $Post$, $enterItem() \sqsubseteq enterItem'()$ and $makePayment() \sqsubseteq makePayment'()$. By applying **Law 4** we have $POST2 \sqsubseteq POST3$.

We will still use unprimed names $enterItem()$ and $makePayment()$ to denote the newly refined methods in $POST3$. We make this abuse only for avoiding too many notations. In the rest of this paper we will adopt this abuse where no confusion will be made. The corresponding class diagram of $POST3$ is depicted in Fig. 4.

Next, we will continue to delegate the tasks of $Sale$ to $ProductCatalog$ and $Payment$. Similar to the above process, we develop a new method $Search()$ in class $ProductCatalog$ and invoke it in the method $makeLineItem()$ of class $Sale$. Let us see the specification of the new method:

$Search(UPC\ upc, ProductSpecification\ ps)$:

$$pslist \neq nil \vdash (ps' = null) \triangleleft (\exists ps \in pslist \wedge ps.upc = upc) \triangleright (ps' = ps)$$

This method searches a valid $Product\ Specification$ from $ProductCatalog$ and return it when success. Supported by this method, we can implement the method $makeLineItem$ in class $Sale$ as follows:

```
makeLineItem'( UPC upc, int quantity) =
  {var ProductSpecification ps;
   Search(upc, ps);
   (ps ≠ null) ▷ {
     var SalesLineItem sli;
     ProductSpecification.new(sli, [ps, quantity])}
   items.Add(sli);
   end ps}
```

Also, motivated by delegating a task of class $Sale$ to class $Payment$, we develop a new method $pay()$ in the class $Payment$:

$$pay() = \{\{\text{Paid by cash}\} \triangleleft (type = 0) \triangleright \{\text{Paid by credit}\}\}$$

Supported by this method, we implement $makePayment(int\ type)$ in class $Sale$ as

```

Sale.makePayment'( int type) =
  {skip  $\triangleleft$  (type = 0  $\vee$  type = 1) $\triangleright$ }
  {
    var float amount = 0;
    foreach (SaleLineItem item  $\in$  items)
      amount = amount + item.priese*item.quantity;
    Payment.new(payment,[amount,type]);
    ayment.pay()
  }
  }
  
```

In the semantic model we can prove in class *Sale* $makeLineItem() \sqsubseteq makeLineItem'()$ and $makePayment() \sqsubseteq makePayment'()$.

With similar process, we can get a new system as *POST₄* by adding *Search()* to class *ProductCatalog* and *pay()* to class *Payment*, substituting old *makeLineItem()*, *makePayment()* with new ones in class *Sale*. And also, we have $POST_3 \sqsubseteq POST_4$. The corresponding class diagram of *POST₄* is depicted in Fig. 5.

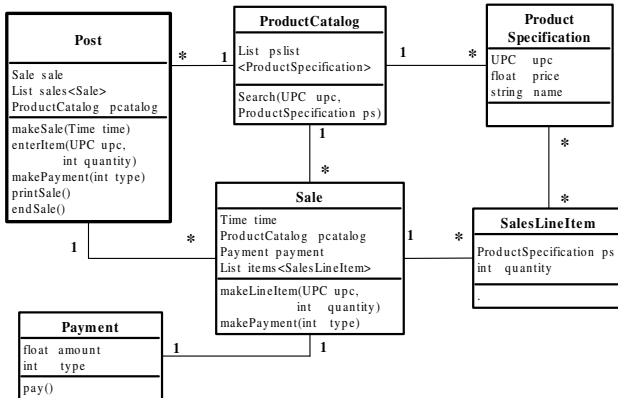

Figure 5: Design Model

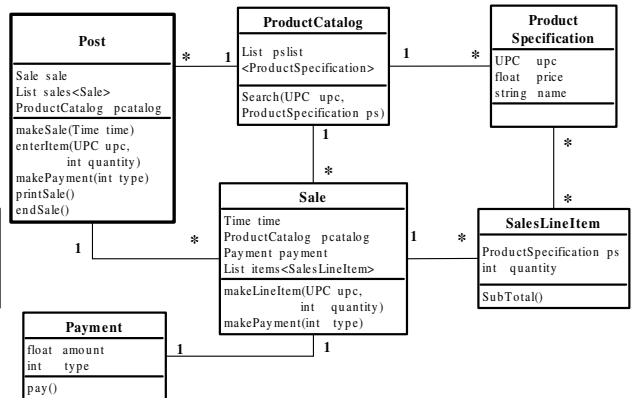

Figure 6: Extract method and Move method

3.5 Refactoring: Extract Method and Move Method

After the efforts, we have reached the *Design Model*. Now we are ready to implement the system with any OO language. But there might be some K. Beck and M. Fowler’s “*bad smells*” [7] existing in the design. In the rest of this section we will refactor the model to enhance the flexibility and maintainability.

After carefully reviewing of the design, we find a piece of typical code needed to be refactored: the method *makePayment()* in class *Sale* uses the attributes of *SalesLineItem* many times. It could be better if the computation happens in *SalesLineItem* itself to reduce the coupling, or interaction, between classes. So we would like to extract a method in class *Sale* and then move it to class *SalesLineItem*.

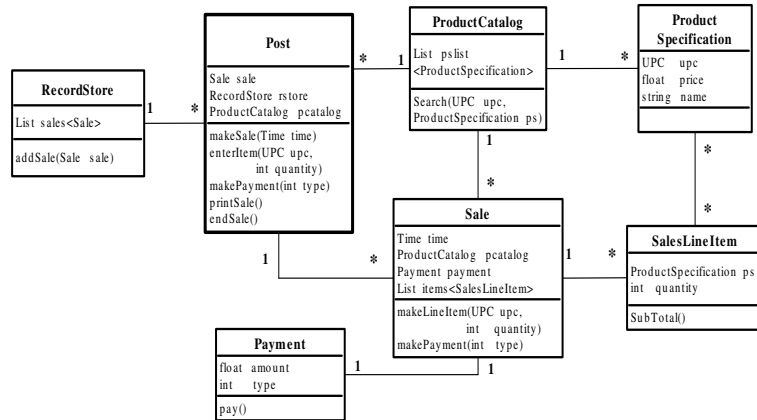

Figure 7: Extract Class

We formally make the refactoring as follows:

Firstly, supported by the **Law 5 (Extract Method)** we have

$$Sale[makePayment()] \sqsubseteq Sale[makePayment() \{ subtotal() \} (item.prise * item.quantity)]$$

where

- $subtotal() = \{\mathbf{return} \ item.prise * item.quantity\}$
- $[a \setminus b]$ means to substitute b with a .

The right hand can be refactorred further. With the **Law 6 (Move Method)** we have

$$Sale[makePayment()]; SalesLineItem[] \sqsubseteq Sale[makePayment() \{ item.subtotal() \} subtotal()]; SalesLineItem[subtotal()]$$

where, in the class *SalesLineItem*, $subtotal() = \{\mathbf{return} \ prise * quantity\}$.

Thus we get the new class declarations *POST5* whose corresponding class diagram is depicted in Fig. 6. Again, we have $POST_4 \sqsubseteq POST_5$.

3.6 Refactoring: Extract Class

Next, we have a closer look at the class *Post*. It has an attribute *sales* which is a list to record all the past sales. For one thing, it is not suitable to let the interface class maintain such a long

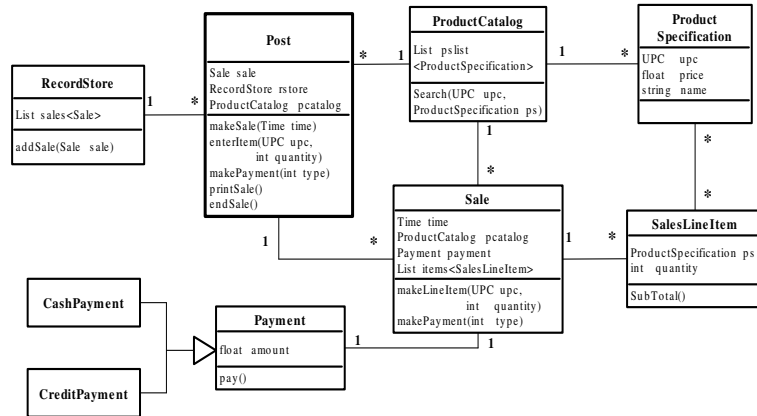

Figure 8: Strategy Pattern-Directed Refactoring

list. For another, there may be several instances of *Post* working parallelly. They should share the same list¹. So we need another class to maintain the list. We would like to extract a new class *RecordStore* to do the job instead.

Supported by the **Law 7 (Extract Class)** we have

$$Post[List\ sales(Sale)] \sqsubseteq Post[RecordStore\ rstore]; RecordStore[List\ sales(Sale)]$$

Similar to subsection 3.5, we can extract a method *addSale(Sale sale)* in class *Post*, which adds the current *sale* object to the sales list *rstore.sales*. And then, we move it to the newly developed class *RecordStore*, and have the class diagram in Fig. 7. We denote the corresponding class declarations as *POST6* and again *POST5* \sqsubseteq *POST6*.

3.7 Pattern-Directed Refactoring: Strategy

Now it comes to the last phase of the refinement. This is a pattern-directed refactoring in which we introduce *Strategy* design pattern to the existing system.

In method *pay()* of class *Payment*, we have a piece of code “ $c_1 \triangleleft type = 0 \triangleright c_2$ ” in which the value of *type* will affect the behavior of the method. Now, directed by *Strategy Pattern*, we would like to refactor it by replacing the type code with polymorphism.

¹This list can be considered as a database for all the records.

Supported by **Law 8 (Strategy)** we have

$$\begin{aligned} & Sale[makePayment(int\ type)];\ Payment[int\ type, pay()] \sqsubseteq \\ & Sale[makePayment(int\ type)];\ Payment[pay()]; \\ & CashPayment[Payment, pay()];\ CreditPayment[Payment, pay()] \end{aligned}$$

where

- The method *makePayment(int type)* on the right hand is different to the one on the left hand. We delete the command “*Payment.new(payment, [amount, type]);*” from the old method and substitute it with another command:

$$\begin{aligned} & CashPayment.new(payment, [amount]) \triangleleft (type = 0) \triangleright \\ & CreditPayment.new(payment, [amount]); \end{aligned}$$

- The method body of *pay()* in class *Payment* is empty. It is implemented by its subclasses.
- In class *CashPayment*, method *pay()* = {Paid by cash}, and in class *CreditPayment*, method *pay()* = {Paid by credit}.

Now the type code is replaced by polymorphism by introducing two subclasses. We denote the new class declarations as *POST7*, and have *POST6* \sqsubseteq *POST7*. The class diagram is depicted in Fig. 8.

After the above refinement process, we gain the final design *POST7* from *POST0*. This ends our refinement. The classes in the final design is very near to executable code. It is easy to implement it in any OO programming languages. We have implemented it using Visual C# .Net.

4 Implementation: Final Product

Supported by the C# and the .Net developing environment, we implement an executable software product for the final design model.

The main interface of the system, depicted in Fig. 9, is composed of five “Button”s which represent the five methods in class *Post*. Also we have two “TextBox”s to input the UPC and quantity of the current purchasing product, a “ListBox” to show the content of the current *sale*, and a pair of “RadioButton”s to choose payment ways. After the payment way is chosen, when the “Print Sale” button is pressed, the system will pop-up a form to show the receipt for customers.

An executing snapshot of our software is depicted in Fig. 10.

5 Conclusions and Future Work

As stated in the introduction, the main motivation of this paper is to show the power of rCOS refinement calculus in incremental software development by presenting the POST case study. From this study, we could draw the conclusions about the advantages, and a tiny disadvantage as well, of rCOS.

- As we have shown in the refinement process, rCOS supports a wide range of object-oriented techniques. So it is a suitable calculus for OO development.
- In the rCOS based software development, we can prove the correctness of each developing step. So at least for highly critical systems, rCOS is a useful supporting model. Further, in teamwork of large scale software development, rCOS also offers a robust support for rigorous correctness formal proof.
- It is proven that rCOS can be used as a formal framework for the *use-cased driven*, *incremental* and *iterative* Rational Unified Process (RUP). And also, the rCOS based process is practical and scalable in software engineering.
- In practice, rCOS also offers a nice semantic model for correctly refactoring the existing design, and further, might give a choice for refactoring supporting tools development.
- The limitations. During the development of the POST system, we realized that there are some tiny limitations existing in the current version of rCOS. For instance, we do not have exception handling in the syntax of rCOS, making no chance to use such mechanism to deal with dynamic errors in the software development.

As for the future work, we would like to provide tool support for our refinement calculus. We hope, given the proof obligation of a refinement equation, the tool can search whether there is a refinement law syntactically matches. Another important future work is, as mentioned above, we need to extend the current version of rCOS to support more features, such as exception handling, of OO programming languages. There, we believe, will be no essential difficulty.
